Magnesium in biology Wikipedia
November 13th, 2018 - Magnesium is a relatively abundant ion in Earth s crust and mantle and is highly bioavailable in the hydrosphere This availability in combination with a useful and very unusual chemistry may have led to its utilization in evolution as an ion for signaling enzyme activation and catalysis However the unusual nature of ionic magnesium has also led to a major challenge in the use of the ion in biological systems

Magnesium The Royal Society of Chemistry
October 15th, 2018 - Magnesium is the eighth most abundant element in the Earthâ€™s crust but does not occur uncombined in nature It is found in large deposits in minerals such as magnesite and dolomite The sea contains trillions of tonnes of magnesium and this is the source of much of the 850 000 tonnes now produced each year
